

**Cover image:** Pictured is an artificial eye that was inspired by the elephantnose fish (*Gnathonemus petersii*) retina and designed for low-light imaging. Hwei Liu et al. constructed the imaging device with an iris-mounted ball lens, a clear protective shell, and a photosensitive enhancer, which contains an array of elephantnose-like funnel-shaped microphotocollectors. The device helps visualize spatial features and boundaries of objects in low-light settings and across a wide light spectrum, and could be used to improve night-vision cameras, medical instruments, robotics, and space exploration. See the article by Hwei Liu et al. on pages 3982–3985. Image courtesy of Hongrui Jiang and Hwei Liu.
