Edited by John Hagan, Northwestern University, Evanston, IL, and approved July 3, 2019 (received for review December 12, 2018)

We use data on police-involved deaths to estimate how the risk of being killed by police use of force in the United States varies across social groups. We estimate the lifetime and age-specific risks of being killed by police by race and sex. We also provide estimates of the proportion of all deaths accounted for by police use of force. We find that African American men and women, American Indian/Alaska Native men and women, and Latino men face higher lifetime risk of being killed by police than do their white peers. We find that Latina women and Asian/Pacific Islander men and women face lower risk of being killed by police than do their white peers. Risk is highest for black men, who (at current levels of risk) face about a 1 in 1,000 chance of being killed by police over the life course. The average lifetime odds of being killed by police are about 1 in 2,000 for men and about 1 in 33,000 for women. Risk peaks between the ages of 20 y and 35 y for all groups. For young men of color, police use of force is among the leading causes of death.

criminal justice | public health | demography | social inequality

Violent encounters with the police have profound effects on health, neighborhoods, life chances, and politics (1–9). Policing plays a key role in maintaining structural inequalities between people of color and white people in the United States (1, 10). The killings of Oscar Grant, Michael Brown, Charleena Lyles, Stephon Clark, and Tamir Rice, among many others, and the protests that followed have brought sustained national attention to the racialized character of police violence against civilians (11). Social scientists and public health scholars now widely acknowledge that police contact is a key vector of health inequality (3, 6) and is an important cause of early mortality for people of color (12).

Police in the United States kill far more people than do police in other advanced industrial democracies (13). While a substantial body of evidence shows that people of color, especially African Americans, are at greater risk for experiencing criminal justice contact and police-involved harm than are whites (14–19), we lack basic estimates of the prevalence of police-involved deaths, largely due to the absence of definitive official data. Journalists have stepped into this void and initiated a series of systematic efforts to track police-involved killings. These data enable a richer understanding of the geographic and demographic patterning of police violence (17) and an evaluation of the magnitude of exposure to police violence over the life course.

Prior research has clearly established that race, sex, and age are closely correlated with exposure to the criminal justice system (20–22). Age, race, and gender are also central to the logics that police and legal systems use to decide who to target, how to intervene, and how much force should be applied in the process of policing (5, 23–26).

Research Strategy and Key Findings

This paper provides descriptive estimates of the national prevalence of fatal police violence. In doing so, we contribute to a body of research that uses demographic methods to systematically describe the depth of the involvement of the criminal justice system in the lives of Americans (22, 27–30).

We estimate the risk of being killed by police use of force in the United States by age, race, and sex. We also construct period life tables (31) that provide estimates of the risk of death across the life course, with the central assumption that risk profiles observed between 2013 and 2018 remain stable. We use Bayesian simulation and multilevel models to provide uncertainty intervals for our mortality estimates.

Our results show that people of color face a higher likelihood of being killed by police than do white men and women, that risk peaks in young adulthood, and that men of color face a nontrivial lifetime risk of being killed by police.

Focal measures for this analysis rely on data compiled by Fatal Encounters (FE) (32), a journalist-led effort to document deaths involving police. Cases are identified through public records and news coverage, and each variable in the data is validated against published documents. Unofficial media-based methods provide more comprehensive information on police violence than do the limited official data currently available (4, 33, 34).

We focus exclusively on police use-of-force deaths and exclude cases from the analysis that police described as a suicide, that involved a vehicular collision, or that involved an accident such as an overdose or a fall. We provide sensitivity analyses that explore the impact of these inclusion criteria in *SI Appendix, Fig. S12*. Mortality rate estimates for all groups increase substantially when all recorded cases are included in the analysis.

We describe the data and methods, their limitations, and their assumptions in more detail in *Materials and Methods* and in *SI Appendix*.

Results

Fig. 1 displays estimates of lifetime risk of being killed by police use of force by race and sex, using data from 2013 to 2018. We

Significance

Police violence is a leading cause of death for young men in the United States. Over the life course, about 1 in every 1,000 black men can expect to be killed by police. Risk of being killed by police peaks between the ages of 20 y and 35 y for men and women and for all racial and ethnic groups. Black women and men and American Indian and Alaska Native women and men are significantly more likely than white women and men to be killed by police. Latino men are also more likely to be killed by police than are white men.

Fig. 1. Lifetime risk of being killed by the police in the United States by sex and race-ethnicity for a synthetic cohort of 100,000 at 2013 to 2018 risk levels. Dashes indicate 90% posterior predictive uncertainty intervals. Life tables were calculated using model-based simulations from 2013 to 2018 Fatal Encounters data and 2017 National Vital Statistics System data.

estimate that over the life course, at levels of risk similar to those observed between 2013 and 2018, about 52 [39, 68] (90% uncertainty interval) of every 100,000 men and boys in the United States will be killed by police use of force over the life course, and about 3 [1.5, 4.5] of every 100,000 women and girls will be killed by police over the life course.

Fig. 2 displays the ratio of lifetime risk for each racial-ethnic group relative to risk for whites for both men and women. Note that a rate ratio of 1 indicates equality in mortality risk relative to whites. The highest levels of inequality in mortality risk are experienced by black men. Black men are about 2.5 times more likely to be killed by police over the life course than are white men. Black women are about 1.4 times more likely to be killed by police than are white women. Although risks are estimated with less precision for American Indian/Alaska Native men and women than for other groups, we show that they face a higher lifetime risk of being killed by police than do whites. American Indian men are between 1.2 and 1.7 times

more likely to be killed by police than are white men, and American Indian women are between 1.1 and 2.1 times more likely to be killed by police than are white women. Latino men are between 1.3 and 1.4 times more likely to be killed by police than are white men, but Latina women are between 12% and 23% less likely to be killed by police than are white women. Both Asian/Pacific Islander men and women are more than 50% less likely to be killed by police than are white men and women, respectively.

Among all groups, black men and boys face the highest lifetime risk of being killed by police. Our models predict that about 1 in 1,000 black men and boys will be killed by police over the life course (96 [77, 120] per 100,000). We predict that between 36 and 81 American Indian/Alaska Native men and boys per 100,000 will be killed by police over the life course. Latino men and boys have an estimated risk of being killed by police of about 53 per 100,000 [41, 67]. Asian/Pacific Islander men and boys face a lifetime risk of between 9 and 23 per 100,000, while

0.16% of all deaths of Latina women, and 0.11% of all deaths of white women.

Discussion

Our analysis shows that the risk of being killed by police is jointly patterned by one's race, gender, and age. Police violence is a leading cause of death for young men, and young men of color face exceptionally high risk of being killed by police. Inequalities in risk are pronounced throughout the life course. This study reinforces calls to treat police violence as a public health issue (1, 4). Racially unequal exposure to the risk of state violence has profound consequences for public health, democracy, and racial stratification (5, 7–9, 11).

Results should be interpreted with several considerations in mind. While the methods used in this paper allow for nationally precise age-, race-, and gender-specific mortality estimates, they may mask important subnational variation and changes in risk over time (17, 36). Because our analysis focuses on some groups that have low age-specific risks, we lack the power to closely consider spatial and temporal trends. However, in *SI Appendix, Fig. S3* we show that rates of death have increased by as much as 50% since 2008. Also note that while black people remain disproportionately more likely than white people to be killed by police, the share of white deaths has been increasing in recent years (*SI Appendix, Fig. S5*). Our approach smooths over these changes by treating year effects as random error, but future research should examine these trends closely. Prior research suggests that despite high contemporary rates, the risk of being killed by police was higher in decades past (37).

FE relies on photographs and victim obituaries to classify the race-ethnicity of victims. FE does not currently collect data on variables that may be associated with variation in risk within racial/ethnic groups such as skin tone, multiracial identity, or social class (38). We discuss FE's methodology and compare

FE's racial data to other sources of data in *SI Appendix, Figs. S5 and S7*. The meaning of race, age, and gender for police violence emerges in the interactions between how officers perceive an individual's identity and the salience of these classifications for perceptions of criminality, belonging, and dangerousness (1, 10, 25, 39). Future work should closely consider how place, race, gender, age, social class, and disability intersectionally structure exposure to violence (26).

The absence of authoritative official data is a key challenge in reducing police violence. The Bureau of Justice Statistics should renew efforts to develop comprehensive systems to track officer-involved deaths (4, 40). Both the public interest and social science are served by increasing transparency with regard to police use of force. Using such data, the research community has made strides in identifying officers most at risk of being involved in cases of excessive force (41) and system failures that result in civilian deaths (42).

While our research does not evaluate the effects of policy, we believe that several avenues of reform may be fruitful in reducing rates of death. Austerity in social welfare and public health programs has led to police and prisons becoming catch-all responses to social problems (43, 44). Adequately funding community-based services and restricting the use of armed officers as first responders to mental health and other forms of crisis would likely reduce the volume of people killed by police (44). Increasing the ability of the public to engage in the regulation of policing through both investigatory commissions with disciplinary teeth and equal participation in police union contract negotiations would also likely reduce rates of death (45).

Materials and Methods

Our analysis relies on a combination of official and unofficial sources of mortality data: FE and the National Vital Statistics System (NVSS) (46). FE collects data on all deaths involving police through systematic searches of online news coverage, public records, and social media. FE provides more

Fig. 5. Deaths caused by police use of force (median model-based prediction) as a percentage of all deaths by age, race, and sex. Life tables were calculated using model simulations from 2013 to 2018 Fatal Encounters data and 2017 National Vital Statistics System data.

comprehensive data on police-involved deaths than do official mortality files (34), has a broader scope than similar unofficial efforts to document deaths, and has been endorsed as a sound source of data by the Bureau of Justice Statistics (47). Despite the relatively high quality of FE, because the data rely on media reports, counts of deaths are likely negatively biased. If any death is not covered by news organizations or is not documented in searchable public records, it will not appear in the data.

Between 2013 and 2018, about 9% of FE cases are missing data on race-ethnicity (*SI Appendix, Table S1*). We use multiple imputation by chained equations (48) to address missing data for observations between 2013 and 2018. Imputation models include victim age, sex, race, cause of death, and the racial/ethnic composition of the county in which a death occurred. We also include surname-specific estimates of the probability of racial/ethnic group identification on the US Census compiled by Imai and Khanna (49). Results yield similar case compositions to those we observe in NVSS and FE data, as shown in *SI Appendix, Fig. S7*. Listwise deletion of missing cases unrealistically understates uncertainty in our parameter estimates and negatively biases mortality risk estimates (*SI Appendix, Fig. S8*).

We use these imputed data to construct multilevel Bayesian count models of mortality risk that allow us to directly estimate uncertainty driven by small annual age-race-sex-specific death counts for some groups, by

variation in underlying risk over the 6 y of FE data, and by missing data. Intervals reported in the text are drawn from model posterior predictive distributions.

Because we lack sufficient data to track a birth cohort over the life course, we rely on synthetic cohorts to estimate lifetime risk (31). Period life tables allow us to estimate deaths over the life course within a compressed period by tracking age-specific mortality risk over hypothetical cohorts in each subgroup with the key assumption that underlying age-specific mortality risks remain constant at observed levels throughout the life course. All risk estimates presented in this paper can be interpreted as estimates of age-specific or cumulative lifetime risk at 2013 to 2018 police use-of-force mortality rates and 2017 total mortality rates. Our methods are described in more detail in *SI Appendix*, and an excerpt of our multiple-decrement period life table is displayed in *SI Appendix, Table S4*.

A replication package containing all scripts and data used in this analysis is available through an Open Science Framework project repository (<https://osf.io/c8qhx/>).
