

**Cover image:** Pictured is a male mimic poison frog (*Ranitomeya imitator*), a monogamous amphibian, carrying a tadpole. Rebecca L. Young et al. compared the neural transcriptomes of monogamous and nonmonogamous male vertebrates, including birds, fishes, frogs, mice, and voles, and found a shared gene expression signature among monogamous species. The authors also highlighted 24 genes that were associated with monogamy. The findings suggest that diverse vertebrate species experienced similar gene expression changes as they evolved to become monogamous. See the article by Young et al. on pages 1331–1336.
